This is a pre-print of an article published in *Functiones et Approximatio, Commentarii Mathematici*. © 2016. All rights reserved. doi: [10.7169/facm/2016.54.2.7](https://doi.org/10.7169/facm/2016.54.2.7)

COMPARING LOCAL CONSTANTS OF ORDINARY ELLIPTIC CURVES IN DIHEDRAL EXTENSIONS

SUNIL CHETTY

ABSTRACT. We establish, for a substantial class of elliptic curves, that the arithmetic local constants introduced by Mazur and Rubin agree with quotients of analytic root numbers.

1. INTRODUCTION

Let E/k be an elliptic curve over a number field k . Fix a rational prime $p > 3$ for which E is ordinary¹ and a quadratic extension K of k . Next, fix a character ρ of $\text{Gal}(\bar{k}/K)$ of order p^n and let $\tau_\rho = \text{ind}_{K/k} \rho$ and $\tau_1 = \text{ind}_{K/k} 1$ be the induced representations² from $\text{Gal}(\bar{k}/K)$ to $\text{Gal}(\bar{k}/k)$. With ρ we define $L = \bar{k}^{\ker(\rho)}$, a cyclic extension L/K of degree p^n , and we assume ρ is such that L/k is Galois and that the non-trivial element $c \in \text{Gal}(K/k)$ acts on $g \in \text{Gal}(L/k)$ via conjugation as $cgc^{-1} = g^{-1}$. Following [9] we refer to such extensions L/k as dihedral.

Let v denote a prime of K , u the prime of k below v , w a prime of L above v , and denote k_u , K_v and L_w for the completions at u , v , and w . We consider $\text{Gal}(L_w/k_u) \leq \text{Gal}(L/k)$, and we set $\tau_{\rho,u}$ (resp. $\tau_{1,u}$) to be τ_ρ (resp. τ_1) restricted to $\text{Gal}(L_w/k_u)$.

For a self-dual complex representation τ of $\text{Gal}(L/k)$, one has a conjectural functional equation for the completed L -function $\Lambda(E/k, \tau, s)$ (see [12, §21])

$$(1.1) \quad \Lambda(E/k, \tau, s) = \left(\prod_u W(E/k_u, \tau_u) \right) \Lambda(E/k, \tau, 2-s),$$

with $W(E/k_u, \tau_u) \in \{\pm 1\}$ and the product taken over places u of k . Even though the functional equation is conjectural, the $W(E/k_u, \tau_u)$ can often be made explicit.

In [9] Mazur and Rubin define constants δ_v , for each prime v of K , which relate the ρ -part and 1-part of the pro- p -Selmer $\text{Gal}(\bar{k}/K)$ -module $\mathcal{S}_p(E/L)$ (see §2.2)

$$(1.2) \quad \dim_{\mathbb{Q}_p} \mathcal{S}_p(E/L)^\rho - \dim_{\mathbb{Q}_p} \mathcal{S}_p(E/L)^1 \equiv \sum_v \delta_v \pmod{2}.$$

¹There is, to date and to our knowledge, only one result [9, Theorem 5.7] at supersingular primes analogous to our considerations.

²Context will determine the field of values. See [7, §5] for a discussion of this.

Defining γ_u by $(-1)^{\gamma_u} = W(E/k_u, \tau_{\rho, u})/W(E/k_u, \tau_{1, u})$, for each prime u of k , the invariance of $\Lambda(E/k, \tau, s)$ under induction (see [12, §8]) and (1.1) give

$$(1.3) \quad \text{ord}_{s=1} \Lambda(E/k, \tau_{\rho}, s) - \text{ord}_{s=1} \Lambda(E/k, \tau_1, s) \equiv \sum_u \gamma_u \pmod{2}.$$

With the Shafarevic-Tate and Birch-Swinnerton-Dyer Conjectures in mind, the left-hand sides of (1.2) and (1.3) are equal, and so we aim to show in as many cases as possible that $\gamma_u = \sum_{v|u} \delta_v$.

Our main new result is Theorem 4.1, and it yields a new proof of a case of a relative version of the Parity Conjecture, Corollary 4.2. This Corollary is already known by different methods via work by de la Rochefoucauld in [1], Dokchitser and Dokchitser in [3] and [2], and can also be recovered from work by Greenberg in [5, §13]. Our calculations of δ_v in bad reduction also provide a new extension of the results of [9, §7-8] regarding growth in rank of $\mathcal{S}_p(E)$ over dihedral L/K , for example by relaxing the conditions in Theorem 8.5 of [9].

2. LOCAL CONSTANTS OF ELLIPTIC CURVES

In this section we recall the relevant parts of [13] and [9].

2.1. Analytic Local Constants. We denote ω_u for the standard valuation on k_u and c_6 for the constant appearing in a simplified Weierstrass model for E/k_u (see [17, §III.1]). For τ a representation of $\text{Gal}(\bar{k}_u/k_u)$ with real-valued character, we call $W(E/k_u, \tau) \in \{\pm 1\}$ the analytic local root number for the pair $(E/k_u, \tau)$. We call the constants $\gamma_u \in \mathbb{Z}/2\mathbb{Z}$ defined as quotients of local root numbers in §1 the analytic local constants.

When τ has finite image, set $\mathfrak{c}(\tau) := \det(\tau)(-1)$ and for two representations τ and τ' of $\text{Gal}(\bar{k}_u/k_u)$ with finite image define $\langle \tau, \tau' \rangle := \langle \text{tr}(\tau), \text{tr}(\tau') \rangle$, with the right-hand side the usual inner product on characters.

Let H be the unramified quadratic extension of k_u and η the unramified quadratic character of $\text{Gal}(\bar{k}_u/k_u)$, i.e. the character of $\text{Gal}(\bar{k}_u/k_u)$ with kernel $\text{Gal}(\bar{k}_u/H)$. For $e = 3, 4$, or 6 and $q \equiv -1 \pmod{e}$, where $q = \#(k_u/u)$, let φ_e be a tamely ramified character of $\text{Gal}(\bar{k}_u/H)$ with $\varphi_e|_{\mathcal{O}_H^\times}$ of exact order e and such that $\sigma_e = \text{ind}_{H/k} \varphi_e$ is irreducible and symplectic. For θ the unramified quadratic character of $\text{Gal}(\bar{k}_u/H)$ set $\hat{\sigma}_e := \text{ind}_{H/k_u}(\varphi_e \theta)$, which is a dihedral representation of $\text{Gal}(\bar{k}_u/k_u)$ (see p. 316-318 of [13]).

Define a representation σ_{E/k_u} by applying the results of [12, §4] to

$$\sigma_{E/k_u, \ell} : \text{Gal}(\bar{k}_u/k_u) \rightarrow \text{GL}(V_\ell(E)^*),$$

where $V_\ell(E)^*$ is the dual of $V_\ell(E) = T_\ell(E) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$. From

$$W(E/k_u, \tau) = W(\sigma_{E/k_u} \otimes \tau),$$

Rohrlich proves the following formulae.

Theorem 2.1 (Theorem 2 of [13]). *Suppose $\tau = \bar{\tau}$ is a 2-dimensional representation of $\text{Gal}(\bar{k}_u/k_u)$ and denote ℓ for the residue characteristic of k_u .*

- (i) *If $\ell = \infty$ then $W(E/k_u, \tau) = (-1)^{\dim \tau} = 1$.*
- (ii) *If $\ell < \infty$ and E has good reduction over k_u then $W(E/k_u, \tau) = \mathfrak{c}(\tau)$.*

(iii) If $\ell < \infty$ and $\omega_u(j) < 0$ then

$$W(E/k_u, \tau) = \mathbf{c}(\tau)(-1)^{\langle \chi, \tau \rangle}$$

where χ is the character associated to the extension $k_u(\sqrt{-c_6})$.

(iv) If $5 \leq \ell < \infty$, $\omega_u(j) \geq 0$, and $e = \frac{12}{\gcd(\omega_u(\Delta_E), 12)}$

$$W(E/k_u, \tau) = \begin{cases} \mathbf{c}(\tau) & \text{if } q \equiv 1 \pmod{e} \\ \mathbf{c}(\tau)(-1)^{\langle 1, \tau \rangle + \langle \eta, \tau \rangle + \langle \hat{\sigma}_e, \tau \rangle} & \text{if } e > 2, q \equiv -1 \pmod{e}. \end{cases}$$

Proposition 2.2 (Proposition 7 of [13]). *If $\sigma_{E/k_u} = \psi \oplus \psi^{-1}$ for some character ψ of k_u^\times and τ is as in Theorem 2.1, then $W(E/k_u, \tau) = \mathbf{c}(\tau)$.*

2.2. Arithmetic Local Constants. Let $\text{Sel}_{p^\infty}(E/K)$ be the p^∞ -Selmer group of E (see [9, §2] or [4, §2]). Define the pro- p Selmer group of E over K as the Pontrjagin dual of $\text{Sel}_{p^\infty}(E/K)$

$$\mathcal{S}_p(E/K) := \text{Hom}(\text{Sel}_{p^\infty}(E/K), \mathbb{Q}_p/\mathbb{Z}_p),$$

and consider it as a $\bar{\mathbb{Q}}_p$ -module by tensoring with $\bar{\mathbb{Q}}_p$.

When $L_w \neq K_v$, let L'_w be the unique subfield of L_w containing K_v with $[L_w : L'_w] = p$, and otherwise let $L'_w := L_w = K_v$.

Definition 2.3 (Corollary 5.3 of [9]). For each prime v of K , define the arithmetic local constant $\delta_v = \delta(v, E, \rho) \in \mathbb{Z}/2\mathbb{Z}$ to be

$$\delta_v := \dim_{\mathbb{F}_p} E(K_v)/(E(K_v) \cap N_{L_w/L'_w} E(L_w)) \pmod{2}.$$

Theorem 2.4 (Theorem 6.4 of [9]). *If S is a set of primes of K containing all primes above p , all primes ramified in L/K , and all primes where E has bad reduction, then*

$$\dim_{\bar{\mathbb{Q}}_p} \mathcal{S}_p(E/L)^\rho - \dim_{\bar{\mathbb{Q}}_p} \mathcal{S}_p(E/L)^1 \equiv \sum_{v \in S} \delta_v \pmod{2}.$$

Proof. Following the notation of [9, §3], let R be the maximal order in the cyclotomic field of p^n -roots of unity, so R has a unique prime \mathfrak{p} above p . Define $\mathcal{I} := \mathfrak{p}^{n-1}$ and define the \mathcal{I} -twist of E by $A := \mathcal{I} \otimes E$ (in the sense of [10] and [9]), an abelian variety with $R \subset \text{End}_K(A)$. We then have

$$\begin{aligned} \dim_{\bar{\mathbb{Q}}_p} \mathcal{S}_p(E/L)^\rho &= \text{corank}_{R \otimes \mathbb{Z}_p} \text{Sel}_{p^\infty}(A/K), \\ \dim_{\bar{\mathbb{Q}}_p} \mathcal{S}_p(E/L)^1 &= \text{corank}_{\mathbb{Z}_p} \text{Sel}_{p^\infty}(E/K). \end{aligned}$$

Thus the conclusion above is equivalent to Theorem 6.4 of [9]

$$\text{corank}_{R \otimes \mathbb{Z}_p} \text{Sel}_{p^\infty}(A/K) - \text{corank}_{\mathbb{Z}_p} \text{Sel}_{p^\infty}(E/K) \equiv \sum_{v \in S} \delta_v \pmod{2}.$$

□

3. LOCAL COMPUTATIONS

We keep the setting and notation of Theorem 2.1 and §1. Recall that c is the non-trivial element of $\text{Gal}(K/k)$.

3.1. Preliminary Calculations.

Proposition 3.1. *If $v^c \neq v$, then $\gamma_u \equiv \delta_v + \delta_{v^c} \equiv 0$.*

Proof. When $v \neq v^c$, we have $\text{Gal}(L_w/k_u) = \text{Gal}(L_w/K_v)$. It follows that $\tau_{\rho,u} = \rho \oplus \rho^{-1}$ and $\tau_{1,u} = 1 \oplus 1$, so $\det(\tau)(-1) = 1$ for $\tau = \tau_{\rho,u}$ or $\tau = \tau_{1,u}$. Also $\langle \psi, \tau \rangle \equiv 0 \pmod{2}$ for $\psi = 1, \eta, \chi$, or $\hat{\sigma}_e$, and by Theorem 2.1, we have $W(E/k_u, \tau) = 1$. Applying Lemma 5.1 of [9] for δ_v finishes the claim. \square

Proposition 3.2. *If $v^c = v$, v is unramified in L/K then $\gamma_u \equiv \sum_{v|u} \delta_v \equiv 0$.*

Proof. In this case, v splits completely in L/K by [9, 6.5(i)], i.e. for every prime w of L lying above v , $L_w = K_v$. Now, we have

$$\tau_{\rho,u}, \tau_{1,u} : \text{Gal}(L_w/k_u) = \text{Gal}(K_v/k_u) \rightarrow \text{GL}_2(\mathbb{C})$$

viewing $\text{Gal}(K_v/k_u)$ as the v -decomposition subgroup of $\text{Gal}(L/k)$. One sees by direct calculation (see for example [14, §5.3]) that $\tau_{\rho,u} \cong \tau_{1,u}$, and by applying Corollary 5.3 of [9] for δ_v the claim follows. \square

3.2. Good Reduction. In the case of good reduction, the arithmetic local constant has been determined by Mazur and Rubin in [9].

Theorem 3.3 (Theorem 5.6 and 6.6 of [9]). *If v is a prime of K with $v \nmid p$, $v = v^c$, v is ramified in L/K , and E has good reduction at v , then $\delta_v \equiv 0$.*

Theorem 3.4 (Theorem 6.7 of [9]). *If $v \mid p$ and E has good ordinary reduction at v , then $\delta_v \equiv 0$.*

For the corresponding situation on the analytic side:

Proposition 3.5. *If E has good reduction over K_v then $\gamma_u \equiv 0$.*

Proof. By Theorem 2.1(ii), it suffices to see $\det(\tau_{\rho,u}) \equiv \det(\tau_{1,u}) \pmod{\mathfrak{p}}$ for some $\mathfrak{p} \mid p$. Fixing a basis for the spaces of ρ and 1 respectively, we have $\rho \equiv 1 \pmod{\mathfrak{p}}$ since L/K is a cyclic p -power extension. This implies $\tau_{\rho,u} \equiv \tau_{1,u} \pmod{\mathfrak{p}}$ (component-wise), viewed as matrices with function-valued entries, and $\det(\tau_{\rho,u}) \equiv \det(\tau_{1,u}) \pmod{\mathfrak{p}}$. \square

3.3. Potential Multiplicative Reduction. Here, in view of Propositions 3.1-3.2, we assume $v^c = v$ and v ramifies in L/K , i.e. $L_w \neq K_v$.

3.3.1. Analytic.

Proposition 3.6. *If E/k_u has potential multiplicative reduction, then $\gamma_u \equiv 0$ if and only if E does not have split multiplicative reduction over K_v .*

Proof. Applying the arguments of Proposition 3.5, it remains to determine $\langle \chi, \tau \rangle$. If E has split multiplicative reduction at u , $\chi = 1$ and since $L_w \neq K_v$, $\dim \tau = 2$. We have $\tau = \tau_{1,u} = 1 \oplus \mu$, with μ the character associated to the extension K_v/k_u . When E has split multiplicative reduction at u , $\chi = 1 \not\cong \mu$ and so $\langle \chi, \tau \rangle = 1$. For the other cases, $\chi \cong \mu$ if and only if K_v/k_u is the quadratic extension over which E acquires split multiplicative reduction. \square

3.3.2. *Arithmetic.*

Proposition 3.7. *If E has potential multiplicative reduction over k_u , then $\delta_v \equiv 0$ if and only if E does not have split multiplicative reduction over K_v .*

Proof. Let H be the quadratic extension over which E attains split multiplicative reduction. If $H = K_v$, there is a $q \in k_u^\times$ such that $E(L_w) \cong L_w^\times/q^{\mathbb{Z}}$ as $\text{Gal}(L_w/K_v)$ -modules, and with the isomorphism defined over K_v (loc. cit. [17]). This case is Lemma 8.4 of [9].

Suppose now that $H \neq K_v$. Define E' to be the quadratic twist of E associated to H/k_u , so that E' has split multiplicative reduction at u , and $E \xrightarrow{\varphi} E'$ is an isomorphism over H . As before, we have a $\text{Gal}(HL_w/k_u)$ -isomorphism

$$\lambda : E'(HL_w) \rightarrow HL_w^\times/q^{\mathbb{Z}},$$

with $q \in k^\times$. Let $\text{Gal}(HL_w/L_w) = \langle \sigma \rangle$ and define the minus-part of HL_w^\times to be

$$(HL_w^\times)^- := \{z \in HL_w^\times : z^\sigma = z^{-1}\}$$

and similarly for all other $\text{Gal}(HL_w/L_w)$ -modules³. The map obtained by precomposing λ with φ restricts to

$$E(L_w) \xrightarrow{\varphi} E'(HL_w)^- \xrightarrow{\lambda} ((HL_w^\times)/q^{\mathbb{Z}})^-.$$

If $q \notin N_{HL_w/L_w}$ then we also have $((HL_w^\times)/q^{\mathbb{Z}})^- \cong (HL_w^\times)^-$. If $q \in N_{HL_w/L_w}$ then the projection of $(HL_w^\times)^-$ has index 2 in $((HL_w^\times)/q^{\mathbb{Z}})^-$, hence prime to p . Both cases will be similar, so we proceed with the former. One has a similar situation with $E(L'_w) \rightarrow (HL'_w)^\times$.

Since these maps commute with $N := N_{HL_w/HL'_w}$, the snake lemma gives

$$[E(L'_w) : N(E(L_w))] = [(HL'_w)^\times : N((HL_w^\times)^-)].$$

We claim that this index is 1, implying $E(K_v) \subseteq E(L'_w) = N(E(L_w))$ and hence

$$\dim_{\mathbb{F}_p} E(K_v)/(E(K_v) \cap N_{L_w/L'_w} E(L_w)) = 0.$$

To see that the index is 1, we note that local class field theory gives an injection

$$((HL'_w)^\times)^-/N((HL_w^\times)^-) \hookrightarrow \text{Gal}(HL_w/HL'_w) = \text{Gal}(L_w/L'_w)^-.$$

Since we know that σ conjugates $\text{Gal}(L_w/L'_w)$ trivially, $\text{Gal}(L_w/L'_w)^-$ is trivial. \square

3.4. Potential Good Reduction. Again, we assume $v^c = v$ and v ramifies in L/K , so $L_w \neq K_v$ as before.

3.4.1. *Analytic.* Denote ℓ for the common residue characteristic of k_u, K_v, L_w , and suppose E/k_u has additive and potential good reduction. Throughout we set H to be the unique unramified quadratic extension of k_u .

Proposition 3.8. *Suppose $v \nmid 6$. If $v \nmid p$ or K_v/k_u is unramified then $\gamma_u \equiv 0$.*

Proof. Here, we use the notation of Theorem 2.1, and from $v \nmid 6$, we have $\ell \geq 5$. For $\tau = \tau_{\rho,u}$ or $\tau = \tau_{1,u}$, we have $\langle 1, \tau \rangle + \langle \eta, \tau \rangle \equiv 0 \pmod{2}$, using that K_v/k_u is unramified for the latter.

In this setting $\hat{\sigma}_e$ is the representation of $\text{Gal}(\bar{k}_u/k_u)$ induced from a character $\hat{\varphi}_e$ of order $e = 3, 4$, or 6 (see [13, p. 332]). Hence, we may view $\hat{\sigma}_e$ as a representation

³For example, restriction of σ gives $\text{Gal}(HL_w/L_w) \cong \text{Gal}(HL'_w/L'_w)$, providing HL'_w a $\text{Gal}(HL_w/L_w)$ -module structure.

of $\text{Gal}(K_1/k_u)$ for some extension K_1/K_v .

Consider $\tau = \tau_{\rho,u}$. Lifting $\hat{\sigma}_e$ and τ to some appropriate extension K_2/k_u , since τ is irreducible, we see $\langle \hat{\sigma}_e, \tau \rangle = 1$ if and only if $\hat{\sigma}_e \cong \tau$. Restricting τ and $\hat{\sigma}_e$ to $\text{Gal}(K_2/K_v)$, these representations decompose as $\tau = \rho \oplus \rho^c$ and $\hat{\sigma}_e = \varphi_e \oplus \varphi_e^c$. The order of ρ is a power of $p \geq 5$ and the order of φ_e is 3, 4, or 6, so $\langle \hat{\sigma}_e, \tau \rangle = 0$. For $\tau = \tau_{1,u}$, we have $\tau = 1 \oplus \eta$ and so $\langle \hat{\sigma}_e, \tau \rangle = 0$. \square

Proposition 3.9. *Suppose $v \nmid 6$ and K_v/k_u is ramified. If E acquires good reduction over an abelian extension of k_u , then $\gamma_u \equiv 0$.*

Proof. Here $\ell \geq 5$, so we are in case (iii) of Theorem 2.1, and the condition that E acquires good reduction over an abelian extension of k_u is equivalent to (see [11, Prop 2]) $\mathcal{W}(M/k_u)$ being abelian, where M is the minimal extension of k_u^{ur} over which E acquires good reduction, and in turn to $\sigma_{E/k_u} = \psi \oplus \psi^{-1}$ for some character ψ of k_u^\times . This gives

$$W(E/k_u, \tau) = \mathfrak{c}(\tau) = \det(\tau)(-1).$$

Applying Proposition 3.5 then gives the result. \square

Proposition 3.10. *If $v \mid 6$ then $\gamma_u \equiv 0$.*

Proof. This is case 2(b) of [1]. De la Rochefoucauld proves this in terms of ϵ -factors as Rohrlch's formula (Theorem 2.1 above) do not apply when E is wildly ramified (see [6, §4]). We note that the dihedral setting is essential in his proof. \square

3.4.2. Arithmetic.

Proposition 3.11. *If $v \nmid p$ and E has additive reduction over K_v then $\delta_v \equiv 0$.*

Proof. If E has additive reduction, then

$$(3.1) \quad E_0(K_v)/E_1(K_v) \cong \tilde{E}_{ns}(\kappa) \cong \kappa^+,$$

with κ , the residue field of K_v , a finite field of characteristic $\ell \neq p$. We recall two facts (see §VII.3 and §VII.6 of [17]),

- (1) $E_1(K_v) \cong \mathbb{Z}_\ell^r \oplus T$ for some finite ℓ -group T .
- (2) $|E(K_v)/E_0(K_v)| \leq 4$.

Since $p \nmid 6\ell$ these two facts yield

$$E(K_v)/pE(K_v) \cong E_0(K_v)/pE_0(K_v) \cong E_1(K_v)/pE_1(K_v) = 0,$$

showing that $E(K_v)$ has no p -subgroups and so $\delta_v \equiv 0$. \square

For \mathcal{K} a finite extension of k_u , denote \tilde{E} for the reduction of E at the prime of \mathcal{K} . If κ is the residue field of \mathcal{K} and E has good ordinary reduction over \mathcal{K} then we say that E has *anomalous* reduction over \mathcal{K} if $\tilde{E}(\kappa)[p] \neq 0$, and we say E has *non-anomalous* reduction otherwise (see [9, App. B], also [8, §1.b]).

Proposition 3.12. *If $v \mid p$, E has additive reduction over K_v , and E attains good, ordinary, non-anomalous reduction over a Galois extension M/K_v , then $\delta_v \equiv 0$.*

Proof. Since E has potential good reduction, M can be chosen so that $[M : K_v]$ is prime to p (see [15, §2] and [16, p.2]). Let E^k denote a model for E defined over k_u , and let E^M denote a model of E defined over M for which E has good, ordinary, non-anomalous reduction. We have an isomorphism $E^k \rightarrow E^M$ defined over M ,

giving $E^k(\mathcal{M}) \cong E^M(\mathcal{M})$, where $\mathcal{M} = ML_w$, and similarly for $\mathcal{M}' = ML'_w$. We denote $\Gamma = \text{Gal}(M/K_v)$ and $H = \text{Gal}(L_w/L'_w)$, and note that

$$\text{Gal}(M/K_v) \cong \text{Gal}(\mathcal{M}'/L'_w) \cong \text{Gal}(\mathcal{M}/L_w), \quad \text{Gal}(L_w/L'_w) \cong \text{Gal}(\mathcal{M}/\mathcal{M}').$$

By Propositions B.2 and B.3 of [9], we have that $N_H : E^M(\mathcal{M}) \rightarrow E^M(\mathcal{M}')$ is surjective, and hence $N_H : E^k(\mathcal{M}) \rightarrow E^k(\mathcal{M}')$ is surjective also. From this and $N_\Gamma \circ N_H = N_H \circ N_\Gamma$ we have

$$(3.2) \quad \begin{aligned} [E^k(L'_w) : N_\Gamma(E^k(\mathcal{M}'))] &= [E^k(L'_w) : N_\Gamma \circ N_H(E^k(\mathcal{M}))] \\ &= [E^k(L'_w) : N_H \circ N_\Gamma(E^k(\mathcal{M}))]. \end{aligned}$$

Since Γ has order prime to p and

$$|\Gamma| \cdot E^k(L'_w) \subset N_\Gamma(E^k(\mathcal{M}')) \subset E^k(L'_w),$$

the first term in (3.2) is prime to p . Since H has order p and

$$N_H \circ N_\Gamma(E^k(\mathcal{M})) \subset N_H(E^k(L_w)) \subset E^k(L'_w),$$

the last term in (3.2) is divisible by some power of p when $N_H(E^k(L_w)) \neq E^k(L'_w)$. Since this is impossible, we must have $N_H(E^k(L_w)) \supset E^k(K_v)$ and $\delta_v \equiv 0$. \square

4. MAIN RESULT

Recall E/k is an elliptic curve ordinary at p . Also recall that γ_u is defined by

$$(-1)^{\gamma_u} = W(E/k_u, \tau_{\rho, u}) / W(E/k_u, \tau_{1, u}).$$

Define $\mathfrak{S} = \{\text{primes } v \text{ of } K : v^c = v, v \text{ ramifies in } L/K, \text{ and } v \mid 6p\}$.

Theorem 4.1. *Fix primes u of k and v of K with $v \mid u$. If $v \in \mathfrak{S}$ suppose that one of the following holds:*

- (a) E has good reduction at v .
- (b) E has potential multiplicative reduction at v ,
- (c) E has additive, potential good reduction at v , and acquires good, non-anomalous reduction over an abelian extension of k_u when $v \mid p$.

Then $\gamma_u \equiv \sum_{v \mid u} \delta_v \pmod{2}$.

Corollary 4.2. *If E/k satisfies the hypothesis of Theorem 4.1, then $(\text{mod } 2)$*

$$\dim_{\mathbb{Q}_p} \mathcal{S}_p(E/L)^p - \dim_{\mathbb{Q}_p} \mathcal{S}_p(E/L)^1 \equiv \text{ord}_{s=1} \Lambda(E/k, \rho, s) - \text{ord}_{s=1} \Lambda(E/k, 1, s).$$

Proof of 4.1. Let v, v^c the primes of K above u . If $v \notin \mathfrak{S}$ then $v^c \neq v$, v is unramified in L/K , or $v \nmid 6p$. If $v^c \neq v$ then we use Proposition 3.1, and if $v^c = v$ is unramified in L/K , Proposition 3.2 gives the claim. For the remainder we may assume $v^c = v$.

In the case $v \nmid 6p$, we have $v \nmid 6$ and $v \nmid p$. If E has good reduction at v then Theorem 3.3 shows $\delta_v \equiv 0$, and Proposition 3.5 gives $\gamma_u \equiv 0$. If E has potential multiplicative reduction then Proposition 3.7 and Proposition 3.6, for δ_v and γ_u , respectively, give the result. Lastly, if E has potential good reduction, then we apply Proposition 3.11 and Proposition 3.8.

For $v \in \mathfrak{S}$, case (a) follows from Theorem 3.4 for δ_v and Proposition 3.5 for γ_u . Case (b) is covered by Proposition 3.7 for δ_v and Proposition 3.6 for γ_u .

For case (c), first consider $v \mid 6$. We apply Proposition 3.10 for γ_u , and since $v \nmid p$, we can apply Proposition 3.11 for δ_v . When $v \mid p$ the condition that E acquires ordinary, non-anomalous reduction allows us to apply Proposition 3.12 for δ_v . In

this case, $v \nmid 6$ and so for γ_u we use Proposition 3.8 when K_v/k_u is unramified or the ‘abelian’ condition and Proposition 3.9 when K_v/k_u is ramified. \square
